| ACT_n | SDRAM activate |
| DQ0–DQ63 | DIMM memory data bus |
| CB0–CB7 | DIMM ECC check bits |
| TDQS0_t–TDQS8_t TDQS0_c– TDQS8_c | Dummy loads for mixed populations of x4 based and x8 based RDIMMs. Not used on UDIMMs. |
| DQS0_t–DQS8_t | SDRAM data strobes (positive line of differential pair) |
| DQS0_c–DQS8_c | SDRAM data strobes (negative line of differential pair) |
| DM0_n–DM8_n, DBI0_n–DBI8_n | SDRAM data masks/data bus inversion (x8-based x64 DIMMs) |
| CK0_t, CK1_t | SDRAM clocks (positive line of differential pair) |
| CK0_c, CK1_c | SDRAM clocks (negative line of differential pair) |

| Pin Name | Description |
|----------|---|
| SCL | I ² C serial bus clock for SPD-TSE |
| SDA | I ² C serial bus data line for SPD-TSE |
| SA0–SA2 | I ² C slave address select for SPD-TSE |
| PARITY | SDRAM parity input |
| VDD | SDRAM I/O and core power supply |
| 12 V | Optional power Supply on socket but not used on UDIMM |
| VREFCA | |
| VSS | Power supply return (ground) |
| VDDSPD | Serial SPD-TSE positive power supply |
| ALERT_n | SDRAM ALERT_n |
| VPP | SDRAM Supply |
| RESET_n | Set DRAMs to a Known State |
| EVENT_n | SPD signals a thermal event has occurred |
| VTT | SDRAM I/O termination supply |
| RFU | Reserved for future use |

NOTE :

- 1) Address A17 is not valid for x8 and x16 based SDRAMs. For UDIMMs this connection pin is NC.
- 2) RAS_n is a multiplexed function with A16.
- 3) CAS_n is a multiplexed function with A15.
- 4) WE_n is a multiplexed function with A14.

5. INPUT/OUTPUT FUNCTIONAL DESCRIPTION

[Table 4] Input/Output Function Description

| Symbol | Type | Function |
|---|------------------|--|
| CK_t, CK_c | Input | Clock: CK_t and CK_c are differential clock inputs. All address and control input signals are sampled on the crossing of the positive edge of CK_t and negative edge of CK_c. |
| CKE, (CKE1) | Input | Clock Enable: CKE HIGH activates and CKE LOW deactivates internal clock signals and device input buffers and output drivers. Taking CKE LOW provides Precharge Power-Down and Self-Refresh operation (all banks idle), or Active Power-Down (row Active in any bank). CKE is synchronous for Self-Refresh exit. After VREFCA and Internal DQ Vref have become stable during the power on and initialization sequence, they must be maintained during all operations (including Self-Refresh). CKE must be maintained high throughout read and write accesses. Input buffers, excluding CK_t, CK_c, ODT and CKE, are disabled during power-down. Input buffers, excluding CKE are disabled during Self-Refresh. |
| CS_n, (CS1_n) | Input | Chip Select: All commands are masked when CS_n is registered HIGH. CS_n provides for external Rank selection on systems with multiple Ranks. CS_n is considered part of the command code. |
| C0, C1, C2 | Input | Chip ID : Chip ID is only used for 3DS for 2,4,8 high stack via TSV to select each slice of stacked component. Chip ID is considered part of the command code. |
| ODT, (ODT1) | Input | On Die Termination: ODT (registered HIGH) enables RTT_NOM termination resistance internal to the DDR4 SDRAM. When enabled, ODT is only applied to each DQ, DQS_t, DQS_c and DM_n/DBI_n/ TDQS_t, NU/TDQS_c (When TDQS is enabled via Mode Register A11=1 in MR1) signal for x8 configurations. For x16 configuration ODT is applied to each DQ, DQSU_t, DQSU_c, DQSL_t, DQSL_c, DMU_n, and DML_n signal. The ODT pin will be ignored if MR1 is programmed to disable RTT_NOM. |
| ACT_n | Input | Activation Command Input : ACT_n defines the Activation command being entered along with CS_n. The input into RAS_n/A16, CAS_n/A15 and WE_n/A14 will be considered as Row Address A16, A15 and A14 |
| RAS_n/A16. CAS_n/A15. WE_n/A14 | Input | Command Inputs: RAS_n/A16, CAS_n/A15 and WE_n/A14 (along with CS_n) define the command being entered. Those pins have multi function. For example, for activation with ACT_n Low, these are Addressing like A16, A15 and A14 but for non-activation command with ACT_n High, these are Command pins for Read, Write and other command defined in command truth table |
| DM_n/DBI_n/ TDQS_t, (DMU_n/ DBIU_n), (DML_n/ DBIL_n) | Input/Output | Input Data Mask and Data Bus Inversion: DM_n is an input mask signal for write data. Input data is masked when DM_n is sampled LOW coincident with that input data during a Write access. DM_n is sampled on both edges of DQS. DM is muxed with DBI function by Mode Register A10,A11,A12 setting in MR5. For x8 device, the function of DM or TDQS is enabled by Mode Register A11 setting in MR1. DBI_n is an input/output identifying whether to store/output the true or inverted data. If DBI_n is LOW, the data will be stored/output after inversion inside the DDR4 SDRAM and not inverted if DBI_n is HIGH. TDQS is only supported in X8 |
| BG0 - BG1 | Input | Bank Group Inputs: BG0 - BG1 define to which bank group an Active, Read, Write or Precharge command is being applied. BG0 also determines which mode register is to be accessed during a MRS cycle. X4/8 have BG0 and BG1 but X16 has only BG0. |
| BA0 - BA1 | Input | Bank Address Inputs: BA0 - BA1 define to which bank an Active, Read, Write or Precharge command is being applied. Bank address also determines which mode register is to be accessed during a MRS cycle. |
| A0 - A17 | Input | Address Inputs: Provide the row address for ACTIVATE Commands and the column address for Read/Write commands to select one location out of the memory array in the respective bank. A10/AP, A12/BC_n, RAS_n/A16, CAS_n/A15 and WE_n/A14 have additional functions. See other rows. The address inputs also provide the op-code during Mode Register Set commands. A17 is only defined for the x4 configurations. |
| A10 / AP | Input | Auto-precharge: A10 is sampled during Read/Write commands to determine whether Autoprecharge should be performed to the accessed bank after the Read/Write operation. (HIGH: Autoprecharge; LOW: no Autoprecharge). A10 is sampled during a Precharge command to determine whether the Precharge applies to one bank (A10 LOW) or all banks (A10 HIGH). If only one bank is to be precharged, the bank is selected by bank addresses. |
| A12 / BC_n | Input | Burst Chop: A12/BC_n is sampled during Read and Write commands to determine if burst chop (on-the-fly) will be performed. (HIGH, no burst chop; LOW: burst chopped). See command truth table for details. |
| RESET_n | Input | Active Low Asynchronous Reset: Reset is active when RESET_n is LOW, and inactive when RESET_n is HIGH. RESET_n must be HIGH during normal operation. RESET_n is a CMOS rail to rail signal with DC high and low at 80% and 20% of VDD. |
| DQ | Input/ Output | Data Input/ Output: Bi-directional data bus. If CRC is enabled via Mode register then CRC code is added at the end of Data Burst. Any DQ from DQ0-DQ3 may indicate the internal Vref level during test via Mode Register Setting MR4 A4=High. During this mode, RTT value should be set to Hi-Z. Refer to vendor specific datasheets to determine which DQ is used. |

[Table 4] Input/Output Function Description

| Symbol | Type | Function |
|--|------------------|---|
| DQS_t, DQS_c, DQSU_t, DQSU_c, DQSL_t, DQSL_c | Input/ Output | Data Strobe: output with read data, input with write data. Edge-aligned with read data, centered in write data. For the x16, DQSL corresponds to the data on DQL0-DQL7; DQSU corresponds to the data on DQU0-DQU7. The data strobe DQS_t, DQSL_t and DQSU_t are paired with differential signals DQS_c, DQSL_c, and DQSU_c, respectively, to provide differential pair signaling to the system during reads and writes. DDR4 SDRAM supports differential data strobe only and does not support single-ended. |
| TDQS_t, TDQS_c | Output | Termination Data Strobe: TDQS_t/TDQS_c is applicable for x8 DRAMs only. When enabled via Mode Register A11 = 1 in MR1, the DRAM will enable the same termination resistance function on TDQS_t/TDQS_c that is applied to DQS_t/DQS_c. When disabled via mode register A11 = 0 in MR1, DM/DBI/TDQS will provide the data mask function or Data Bus Inversion depending on MR5; A11,12,10 and TDQS_c is not used. x4/x16 DRAMs must disable the TDQS function via mode register A11 = 0 in MR1. |
| PAR | Input | Command and Address Parity Input: DDR4 Supports Even Parity check in DRAM with MR setting. Once it's enabled via Register in MR5, then DRAM calculates Parity with ACT_n, RAS_n/A16, CAS_n/A15, WE_n/A14, BG0-BG1, BA0-BA1, A17-A0 and C0-C2 (3DS devices). Command and address inputs shall have parity check performed when commands are latched via the rising edge of CK_t and when CS_n is low. |
| ALERT_n | Input/ Output | Alert : It has multi functions such as CRC error flag, Command and Address Parity error flag as Output signal. If there is error in CRC, then ALERT_n goes LOW for the period time interval and goes back HIGH. If there is error in Command Address Parity Check, then ALERT_n goes LOW for relatively long period until on going DRAM internal recovery transaction is complete. During Connectivity Test mode, this pin works as input. Using this signal or not is dependent on system. In case of not connected as Signal, ALERT_n Pin must be bounded to VDD on board. |
| TEN | Input | Connectivity Test Mode Enable : Required on X16 devices and optional input on x4/x8 with densities equal to or greater than 8Gb.HIGH in this pin will enable Connectivity Test Mode operation along with other pins. It is a CMOS rail to rail signal with AC high and low at 80% and 20% of VDD. Using this signal or not is dependent on System. This pin may be DRAM internally pulled low through a weak pull-down resistor to VSS. |
| NC | | No Connect: No internal electrical connection is present. |
| VDDQ | Supply | DQ Power Supply: 1.2 V +/- 0.06 V |
| VSSQ | Supply | DQ Ground |
| VDD | Supply | Power Supply: 1.2 V ± 0.06 V |
| VSS | Supply | Ground |
| VPP | Supply | DRAM Activating Power Supply: 2.5V (2.375V min, 2.75V max) |
| VREFCA | Supply | Reference voltage for CA |
| ZQ | Supply | Reference Pin for ZQ calibration. |

NOTE :

1) Input only pins (BG0-BG1,BA0-BA1, A0-A17, ACT_n, RAS_n/A16, CAS_n/A15, WE_n/A14, CS_n, CKE, ODT, and RESET_n) do not supply termination.

5.1 Address Mirroring

DDR4 two rank UDIMMs will use address mirroring. DRAMs for even ranks will be placed on the front side of the module. DRAMs for odd ranks will be placed on the back side of the module. Wiring of the address bus will be as defined in Table .

Since the cross-wired pins have no secondary functions, there is no problem in normal operation. Any data written is read the same way. There are limitations however. When writing to the internal registers with a "load mode" operation, the specific address is required. This requires the controller to know if the rank is mirrored or not. There is a bit assignment in the SPD that indicates whether the module has been designed with the mirrored feature or not. See the DDR4 SPD specification for these details. The controller must read the SPD and have the capability of de-mirroring the address when accessing the odd ranks.

[Table 5] DIMM Wiring Definition for Address Mirroring

- 1) Unless otherwise noted, resistor values are 15W ± 5%.
 - 2) ZQ resistors are 240W ± 1%. For all other resistor values refer to the appropriate wiring diagram.
 - 3) For part 2 of 2 the DQ resistors are shown for simplicity but are the same physical components as shown on part 1 of 2.
 - 4) EVENT_n is wired on this design. A standalone SPD may be used as well. No wiring changes are required.

7. ABSOLUTE MAXIMUM RATINGS

[Table 6] Absolute Maximum DC Ratings

| Symbol | Parameter | Rating | Units | NOTE |
|------------------------------------|--|-------------|-------|-------|
| VDD | Voltage on VDD pin relative to Vss | -0.3 ~ 1.5 | V | 1,3 |
| VDDQ | Voltage on VDDQ pin relative to Vss | -0.3 ~ 1.5 | V | 1,3 |
| VPP | Voltage on VPP pin relative to Vss | -0.3 ~ 3.0 | V | 4 |
| V _{IN} , V _{OUT} | Voltage on any pin except VREFCA relative to Vss | -0.3 ~ 1.5 | V | 1,3,5 |
| T _{STG} | Storage Temperature | -55 to +100 | °C | 1,2 |

NOTE :

- 1) Stresses greater than those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect reliability
- 2) Storage Temperature is the case surface temperature on the center/top side of the DRAM. For the measurement conditions, please refer to JESD51-2 standard.
- 3) VDD and VDDQ must be within 300mV of each other at all times; and VREFCA must be not greater than 0.6 x VDDQ, When VDD and VDDQ are less than 500mV; VREFCA may be equal to or less than 300mV
- 4) VPP must be equal or greater than VDD/VDDQ at all times.
- 5) Overshoot area above 1.5 V is specified in 9.3.4, 9.3.5 and 9.3.6.

8. AC & DC OPERATING CONDITIONS

[Table 7] Recommended DC Operating Conditions

| Symbol | Parameter | Rating | | | Unit | NOTE |
|--------|---------------------------|--------|------|------|------|-------|
| | | Min. | Typ. | Max. | | |
| VDD | Supply Voltage | 1.14 | 1.2 | 1.26 | V | 1,2,3 |
| VDDQ | Supply Voltage for Output | 1.14 | 1.2 | 1.26 | V | 1,2,3 |
| VPP | Peak-to-Peak Voltage | 2.375 | 2.5 | 2.75 | V | 3 |

NOTE :

- 1) Under all conditions V_{DDQ} must be less than or equal to V_{DD}.
- 2) V_{DDQ} tracks with V_{DD}. AC parameters are measured with V_{DD} and V_{DDQ} tied together.
- 3) DC bandwidth is limited to 20MHz.

NOTE :
 1) See "Overshoot and Undershoot Specifications" on section 9.3.
 2) The AC peak noise on VREFCA may not allow VREFCA to deviate from VREFCA(DC) by more than ± 1% VDD (for reference : approx. ± 12mV)
 3) For reference : approx. $VDD/2 \pm 12mV$.

9.2 AC and DC Input Measurement Levels: V_{REF} Tolerances.

The DC-tolerance limits and ac-noise limits for the reference voltages V_{REFCA} is illustrated in Figure 1. It shows a valid reference voltage $V_{REF}(t)$ as a function of time. (V_{REF} stands for V_{REFCA}).

$V_{REF}(DC)$ is the linear average of $V_{REF}(t)$ over a very long period of time (e.g. 1 sec). This average has to meet the min/max requirement in Table 8. Furthermore $V_{REF}(t)$ may temporarily deviate from $V_{REF}(DC)$ by no more than ± 1% V_{DD} .

Figure 1. Illustration of $V_{REF}(DC)$ tolerance and V_{REF} AC-noise limits

The voltage levels for setup and hold time measurements $V_{IH}(AC)$, $V_{IH}(DC)$, $V_{IL}(AC)$ and $V_{IL}(DC)$ are dependent on V_{REF} .

" V_{REF} " shall be understood as $V_{REF}(DC)$, as defined in Figure 1.

This clarifies, that DC-variations of V_{REF} affect the absolute voltage a signal has to reach to achieve a valid high or low level and therefore the time to which setup and hold is measured. System timing and voltage budgets need to account for $V_{REF}(DC)$ deviations from the optimum position within the data-eye of the input signals.

This also clarifies that the DRAM setup/hold specification and derating values need to include time and voltage associated with V_{REF} AC-noise. Timing and voltage effects due to AC-noise on V_{REF} up to the specified limit ($\pm 1\%$ of V_{DD}) are included in DRAM timings and their associated deratings.

- NOTE:**
 1) Differential signal rising edge from V_{IL.DIFF.MAX} to V_{IH.DIFF.MIN} must be monotonic slope.
 2) Differential signal falling edge from V_{IH.DIFF.MIN} to V_{IL.DIFF.MAX} must be monotonic slope.

- NOTE :**
 1) Used to define a differential signal slew-rate.
 2) for CK_t - CK_c use V_{IH,CA}/V_{IL,CA(AC)} of ADD/CMD and V_{REFCA};
 3) These values are not defined; however, the differential signals CK_t - CK_c, need to be within the respective limits (V_{IH,CA(DC)} max, V_{IL,CA(DC)}min) for single-ended signals as well as the limitations for overshoot and undershoot.

9.3.3 Single-ended Requirements for Differential Signals

Each individual component of a differential signal (CK_t, CK_c) has also to comply with certain requirements for single-ended signals.

CK_t and CK_c have to approximately reach VSEHmin / VSELmax (approximately equal to the ac-levels (VIH.CA(AC) / VIL.CA(AC)) for ADD/CMD signals) in every half-cycle.

Note that the applicable ac-levels for ADD/CMD might be different per speed-bin etc. E.g., if Different value than VIH.CA(AC100)/VIL.CA(AC100) is used for ADD/CMD signals, then these ac-levels apply also for the single-ended signals CK_t and CK_c.

Figure 3. Single-ended requirement for differential signals.

Note that, while ADD/CMD signal requirements are with respect to VrefCA, the single-ended components of differential signals have a requirement with respect to VDD / 2; this is nominally the same. The transition of single-ended signals through the ac-levels is used to measure setup time. For single-ended components of differential signals the requirement to reach VSELmax, VSEHmin has no bearing on timing, but adds a restriction on the common mode characteristics of these signals.

[Table 11] Single-ended Levels for CK_t, CK_c

| Symbol | Parameter | DDR4-1600/1866/2133 | | DDR4-2400/2666 | | Unit | NOTE |
|------------------|--|---------------------|---------------|----------------|--------------|------|------|

| V _{SEL} | Single-ended low-level for CK_t, CK_c | NOTE3 | (VDD/2)-0.100 | NOTE3 | (VDD/2)-0.95 | V | 1, 2 |

- NOTE :
- 1) For CK_t - CK_c use V_{IH,CA}/V_{IL,CA}(AC) of ADD/CMD;
 - 2) V_{IH}(AC)/V_{IL}(AC) for ADD/CMD is based on V_{REFCA};
 - 3) These values are not defined, however the single-ended signals CK_t - CK_c need to be within the respective limits (V_{IH,CA}(DC) max, V_{IL,CA}(DC)min) for single-ended signals as well as the limitations for overshoot and undershoot.

9.4 Slew Rate Definitions

9.4.1 Slew Rate Definitions for Differential Input Signals (CK)

Input slew rate for differential signals (CK_t, CK_c) are defined and measured as shown in Table 15 and Figure 7.

[Table 15] Differential Input Slew Rate Definition

| Description | Measured | | Defined by |
|--|------------------------|------------------------|--|
| | from | to | |
| Differential input slew rate for rising edge (CK _t - CK _c) | V _{ILdiffmax} | V _{IHdiffmin} | $[V_{IHdiffmin} - V_{ILdiffmax}] / \Delta TR_{diff}$ |
| Differential input slew rate for falling edge (CK _t - CK _c) | V _{IHdiffmin} | V _{ILdiffmax} | $[V_{IHdiffmin} - V_{ILdiffmax}] / \Delta TF_{diff}$ |

NOTE :

1) The differential signal (i.e., CK_t - CK_c) must be linear between these thresholds.

Figure 8. Single-ended Input Slew Rate definition for CMD and ADD

NOTE :

- 1) Single-ended input slew rate for rising edge = $\{V_{IHCA(AC)Min} - V_{ILCA(DC)Max}\} / \Delta T_{Rsingle}$.
- 2) Single-ended input slew rate for falling edge = $\{V_{IHCA(DC)Min} - V_{ILCA(AC)Max}\} / \Delta T_{Fsingle}$.
- 3) Single-ended signal rising edge from $V_{ILCA(DC)Max}$ to $V_{IHCA(DC)Min}$ must be monotonic slope.
- 4) Single-ended signal falling edge from $V_{IHCA(DC)Min}$ to $V_{ILCA(DC)Max}$ must be monotonic slope.

9.5 Differential Input Cross Point Voltage

To guarantee tight setup and hold times as well as output skew parameters with respect to clock, each cross point voltage of differential input signals (CK_t, CK_c) must meet the requirements in Table 16. The differential input cross point voltage VIX is measured from the actual cross point of true and complement signals to the midlevel between of VDD and VSS.

- 1) Used to define a differential signal slew-rate.
 - 2) These values are not defined; however, the differential signals DQS_t - DQS_c, need to be within the respective limits Overshoot, Undershoot Specification for single-ended signals.

9.7.3 Peak voltage calculation method

The peak voltage of Differential DQS signals are calculated in a following equation.

$$VIH.DIFF.Peak Voltage = \text{Max}(f(t))$$

$$VIL.DIFF.Peak Voltage = \text{Min}(f(t))$$

$$f(t) = VDQS_t - VDQS_c$$

The $\text{Max}(f(t))$ or $\text{Min}(f(t))$ used to determine the midpoint which to reference the $\pm 35\%$ window of the exempt non-monotonic signaling shall be the smallest peak voltage observed in all ui's.

Figure 12. Definition of differential DQS Peak Voltage and range of exempt non-monotonic signaling

9.7.4 Differential Input Cross Point Voltage

To achieve tight RxMask input requirements as well as output skew parameters with respect to strobe, the cross point voltage of differential input signals (DQS_t, DQS_c) must meet the requirements in Table 19. The differential input cross point voltage VIX_{DQS} (VIX_{DQS_FR} and VIX_{DQS_RF}) is measured from the actual cross point of DQS_t, DQS_c relative to the VDQSmid of the DQS_t and DQS_c signals.

VDQSmid is the midpoint of the minimum levels achieved by the transitioning DQS_t and DQS_c signals, and noted by VDQSmid. VDQSmid is the difference between the lowest horizontal tangent above VDQSmid of the transitioning DQS signals and the highest horizontal tangent below VDQSmid of the transitioning DQS signals.

A non-monotonic transitioning signal's ledge is exempt or not used in determination of a horizontal tangent provided the said ledge occurs within +/- 35% of the midpoint of either VIH.DIFF.Peak Voltage (DQS_t rising) or VIL.DIFF.Peak Voltage (DQS_c rising), refer to Figure 12. A secondary horizontal tangent resulting from a ring-back transition is also exempt in determination of a horizontal tangent. That is, a falling transition's horizontal tangent is derived from its negative slope to zero slope transition (point A in Figure 13) and a ring-back's horizontal tangent derived from its positive slope to zero slope transition (point B in Figure 13) is not a valid horizontal tangent; and a rising transition's horizontal tangent is derived from its positive slope to zero slope transition (point C in Figure 13) and a ring-back's horizontal tangent derived from its negative slope to zero slope transition (point D in Figure 13) is not a valid horizontal tangent.

- 1) Vix_DQS_Ratio is DQS VIX crossing (Vix_DQS_FR or Vix_DQS_RF) divided by VDQSmid. VDQSmid is the difference between the lowest horizontal tangent above VDQSmid of the transitioning DQS signals and the highest horizontal tangent below VDQSmid of the transitioning DQS signals.
 - 2) VDQSmid will be similar to the VREFDQ internal setting value obtained during Vref Training if the DQS and DQs drivers and paths are matched.
 - 3) The maximum limit shall not exceed the smaller of VIHdiff minimum limit or 50mV.
 - 4) VIX measurements are only applicable for transitioning DQS_t and DQS_c signals when toggling data, preamble and high-z states are not applicable conditions.
 - 5) The parameter VDQSmid is defined for simulation and ATE testing purposes, it is not expected to be tested in a system.

9.7.5 Differential Input Slew Rate Definition

Input slew rate for differential signals (DQS_t, DQS_c) are defined and measured as shown in Figure 13 and Figure 14.

Figure 14. Differential Input Slew Rate Definition for DQS_t, DQS_c

- NOTE :
- 1) Differential signal rising edge from VILDiff_DQS to VIHDiff_DQS must be monotonic slope.
 - 2) Differential signal falling edge from VIHDiff_DQS to VILDiff_DQS must be monotonic slope.

10. AC AND DC OUTPUT MEASUREMENT LEVELS

10.1 Output Driver DC Electrical Characteristics

The DDR4 driver supports two different Ron values. These Ron values are referred as strong(low Ron) and weak mode(high Ron). A functional representation of the output buffer is shown in the figure below. Output driver impedance RON is defined as follows:

The individual pull-up and pull-down resistors ($R_{ON_{Pu}}$ and $R_{ON_{Pd}}$) are defined as follows:

$$R_{ON_{Pu}} = \frac{V_{DDQ} - V_{out}}{|I_{out}|} \quad \text{under the condition that } R_{ON_{Pd}} \text{ is off}$$

$$R_{ON_{Pd}} = \frac{V_{out}}{|I_{out}|} \quad \text{under the condition that } R_{ON_{Pu}} \text{ is off}$$

NOTE :

- 1) The tolerance limits are specified after calibration with stable voltage and temperature. For the behavior of the tolerance limits if temperature or voltage changes after calibration, see following section on voltage and temperature sensitivity (TBD).
- 2) Pull-up and pull-dn output driver impedances are recommended to be calibrated at 0.8 * VDDQ. Other calibration schemes may be used to achieve the linearity spec shown above, e.g. calibration at 0.5 * VDDQ and 1.1 * VDDQ.
- 3) Measurement definition for mismatch between pull-up and pull-down, MMPuPd : Measure RONPu and RONPD both at 0.8*VDD separately; Ronnom is the nominal Ron value

$$MMPuPd = \frac{RONPu - RONPd}{RONNOM} * 100$$

- 4) RON variance range ratio to RON Nominal value in a given component, including DQS_t and DQS_c.

$$MMPudd = \frac{RONPuMax - RONPuMin}{RONNOM} * 100$$

$$MMPddd = \frac{RONPdMax - RONPdMin}{RONNOM} * 100$$

- 5) This parameter of x16 device is specified for Uper byte and Lower byte.

10.1.1 Alert_n output Drive Characteristic

A functional representation of the output buffer is shown in the figure below. Output driver impedance RON is defined as follows:

$$RON_{Pd} = \frac{V_{out}}{|I_{out}|} \text{ under the condition that } RON_{Pu} \text{ is off}$$

| Resistor | Vout | Min | Max | Unit | NOTE |
|-------------------|--------------------------------|-----|-----|------|------|
| RON _{Pd} | V _{OLdc} = 0.1 * VDDQ | 0.3 | 1.2 | 34Ω | 1 |
| | V _{OMdc} = 0.8 * VDDQ | 0.4 | 1.2 | 34Ω | 1 |
| | V _{OHdc} = 1.1 * VDDQ | 0.4 | 1.4 | 34Ω | 1 |

NOTE:
1) VDDQ voltage is at VDDQ DC. VDDQ DC definition is TBD.

10.1.2 Output Driver Characteristic of Connectivity Test (CT) Mode

Following Output driver impedance RON will be applied Test Output Pin during Connectivity Test (CT) Mode. The individual pull-up and pull-down resistors (RONPu_CT and RONPd_CT) are defined as follows:

$$RON_{Pu_CT} = \frac{V_{DDQ} - V_{OUT}}{|I_{out}|}$$

$$RON_{Pd_CT} = \frac{V_{OUT}}{|I_{out}|}$$

Figure 16. Output Driver

| | | VOH _{dc} = 1.1 x V _{DDQ} | 1.9 | 34Ω | 1 |

NOTE :

1) Connectivity test mode uses un-calibrated drivers, showing the full range over PVT. No mismatch between pull up and pull down is defined.

10.2 Single-ended AC & DC Output Levels

[Table 24] Single-ended AC & DC Output Levels

| Symbol | Parameter | DDR4-1600/1866/2133/2400/2666 | Units | NOTE |
|--------------|---|-------------------------------|-------|------|
| $V_{OH}(DC)$ | DC output high measurement level (for IV curve linearity) | $1.1 \times V_{DDQ}$ | V | |
| $V_{OM}(DC)$ | DC output mid measurement level (for IV curve linearity) | $0.8 \times V_{DDQ}$ | V | |
| $V_{OL}(DC)$ | DC output low measurement level (for IV curve linearity) | $0.5 \times V_{DDQ}$ | V | |
| $V_{OH}(AC)$ | AC output high measurement level (for output SR) | $(0.7 + 0.15) \times V_{DDQ}$ | V | 1 |
| $V_{OL}(AC)$ | AC output low measurement level (for output SR) | $(0.7 - 0.15) \times V_{DDQ}$ | V | 1 |

NOTE :

1) The swing of $\pm 0.15 \times V_{DDQ}$ is based on approximately 50% of the static single-ended output peak-to-peak swing with a driver impedance of $RZQ/7\Omega$ and an effective test load of 50Ω to $V_{TT} = V_{DDQ}$.

10.3 Differential AC & DC Output Levels

[Table 25] Differential AC & DC Output Levels

| Symbol | Parameter | DDR4-1600/1866/2133/2400/2666 | Units | NOTE |
|------------------|---|-------------------------------|-------|------|
| $V_{OHdiff}(AC)$ | AC differential output high measurement level (for output SR) | $+0.3 \times V_{DDQ}$ | V | 1 |
| $V_{OLdiff}(AC)$ | AC differential output low measurement level (for output SR) | $-0.3 \times V_{DDQ}$ | V | 1 |

NOTE :

1) The swing of $\pm 0.3 \times V_{DDQ}$ is based on approximately 50% of the static differential output peak-to-peak swing with a driver impedance of $RZQ/7\Omega$ and an effective test load of 50Ω to $V_{TT} = V_{DDQ}$ at each of the differential outputs.

10.4 Single-ended Output Slew Rate

With the reference load for timing measurements, output slew rate for falling and rising edges is defined and measured between $V_{OL(AC)}$ and $V_{OH(AC)}$ for single ended signals as shown in Table 26 and Figure 17.

[Table 26] Single-ended Output Slew Rate Definition

| Description | Measured | | Defined by |
|--|--------------|--------------|--|
| | From | To | |
| Single ended output slew rate for rising edge | $V_{OL(AC)}$ | $V_{OH(AC)}$ | $[V_{OH(AC)} - V_{OL(AC)}] / \Delta TR_{se}$ |
| Single ended output slew rate for falling edge | $V_{OH(AC)}$ | $V_{OL(AC)}$ | $[V_{OH(AC)} - V_{OL(AC)}] / \Delta TF_{se}$ |

NOTE :
 1) Output slew rate is verified by design and characterization, and may not be subject to production test.

Description: SR: Slew Rate
 Q: Query Output (like in DQ, which stands for Data-in, Query-Output)
 se: Single-ended Signals
 For Ron = RZQ/7 setting

NOTE :
 1. In two cases, a maximum slew rate of 12 V/ns applies for a single DQ signal within a byte lane.
 -Case 1 is defined for a single DQ signal within a byte lane which is switching into a certain direction (either from high to low or low to high) while all remaining DQ signals in the same byte lane are static (i.e. they stay at either high or low).
 -Case 2 is defined for a single DQ signal within a byte lane which is switching into a certain direction (either from high to low or low to high) while all remaining DQ signals in the same byte lane are switching into the opposite direction (i.e. from low to high or high to low respectively). For the remaining DQ signal switching into the opposite direction, the regular maximum limit of 9 V/ns applies

10.5 Differential Output Slew Rate

With the reference load for timing measurements, output slew rate for falling and rising edges is defined and measured between VOLdiff(AC) and VOHdiff(AC) for differential signals as shown in Table 28 and Figure 18.

[Table 28] Differential Output Slew Rate Definition

| Description | Measured | | Defined by |
|--|-------------|-------------|--|
| | From | To | |
| Differential output slew rate for rising edge | VOLdiff(AC) | VOHdiff(AC) | $[V_{OHdiff(AC)} - V_{OLdiff(AC)}] / \Delta TR_{diff}$ |
| Differential output slew rate for falling edge | VOHdiff(AC) | VOLdiff(AC) | $[V_{OHdiff(AC)} - V_{OLdiff(AC)}] / \Delta TF_{diff}$ |

NOTE:

1) Output slew rate is verified by design and characterization, and may not be subject to production test.

11.1 Speed Bin Table Note

Absolute Specification

- VDDQ = VDD = 1.20V +/- 0.06 V
- VPP = 2.5V +0.25/-0.125 V
- The values defined with above-mentioned table are DLL ON case.
- DDR4-1600, 1866, 2133, 2400 and 2666 Speed Bin Tables are valid only when Geardown Mode is disabled.

- 1) The CL setting and CWL setting result in tCK(avg).MIN and tCK(avg).MAX requirements. When making a selection of tCK(avg), both need to be fulfilled: Requirements from CL setting as well as requirements from CWL setting.
- 2) tCK(avg).MIN limits: Since CAS Latency is not purely analog - data and strobe output are synchronized by the DLL - all possible intermediate frequencies may not be guaranteed. CL in clock cycle is calculated from tAA following rounding algorithm defined in Section 13.5.
- 3) tCK(avg).MAX limits: Calculate $tCK(avg) = tAA.MAX / CL\ SELECTED$ and round the resulting tCK(avg) down to the next valid speed bin (i.e. 1.5ns or 1.25ns or 1.071ns or 0.937ns or 0.833ns). This result is tCK(avg).MAX corresponding to CL SELECTED.
- 4) 'Reserved' settings are not allowed. User must program a different value.
- 5) 'Optional' settings allow certain devices in the industry to support this setting, however, it is not a mandatory feature. Refer to supplier's data sheet and/or the DIMM SPD information if and how this setting is supported.
- 6) Any DDR4-1866 speed bin also supports functional operation at lower frequencies as shown in the table which are not subject to Production Tests but verified by Design/Characterization.
- 7) Any DDR4-2133 speed bin also supports functional operation at lower frequencies as shown in the table which are not subject to Production Tests but verified by Design/Characterization.
- 8) Any DDR4-2400 speed bin also supports functional operation at lower frequencies as shown in the table which are not subject to Production Tests but verified by Design/Characterization.
- 9) Any DDR4-2666 speed bin also supports functional operation at lower frequencies as shown in the table which are not subject to Production Tests but verified by Design/Characterization.
- 10) DDR4-1600 AC timing apply if DRAM operates at lower than 1600 MT/s data rate.
- 11) Parameters apply from tCK(avg) min to tCK(avg) max at all standard JEDEC clock period values as stated in the Speed Bin Tables.
- 12) CL number in parentheses, it means that these numbers are optional.
- 13) DDR4 SDRAM supports CL=9 as long as a system meets tAA(min).
- 14) Each speed bin lists the timing requirements that need to be supported in order for a given DRAM to be JEDEC compliant. JEDEC compliance does not require support for all speed bins within a given speed. JEDEC compliance requires meeting the parameters for a least one of the listed speed bins.

12. IDD AND IDDQ SPECIFICATION PARAMETERS AND TEST CONDITIONS

12.1 IDD, IPP and IDDQ Measurement Conditions

In this chapter, IDD, IPP and IDDQ measurement conditions such as test load and patterns are defined. Figure 21 shows the setup and test load for IDD, IPP and IDDQ measurements.

- IDD currents (such as IDD0, IDD0A, IDD1, IDD1A, IDD2N, IDD2NA, IDD2NL, IDD2NT, IDD2P, IDD2Q, IDD3N, IDD3NA, IDD3P, IDD4R, IDD4RA, IDD4W, IDD4WA, IDD5B, IDD5F2, IDD5F4, IDD6N, IDD6E, IDD6R, IDD6A, IDD7 and IDD8) are measured as time-averaged currents with all VDD balls of the DDR4 SDRAM under test tied together. Any IPP or IDDQ current is not included in IDD currents.
 - IPP currents have the same definition as IDD except that the current on the VPP supply is measured.
 - IDDQ currents (such as IDDQ2NT and IDDQ4R) are measured as time-averaged currents with all VDDQ balls of the DDR4 SDRAM under test tied together. Any IDD current is not included in IDDQ currents.
- Attention: IDDQ values cannot be directly used to calculate IO power of the DDR4 SDRAM. They can be used to support correlation of simulated IO power to actual IO power as outlined in Figure 22. In DRAM module application, IDDQ cannot be measured separately since VDD and VDDQ are using one merged-power layer in Module PCB.

For IDD, IPP and IDDQ measurements, the following definitions apply:

- “0” and “LOW” is defined as $V_{IN} \leq V_{ILAC(max)}$.
- “1” and “HIGH” is defined as $V_{IN} \geq V_{IHAC(min)}$.
- “MID-LEVEL” is defined as inputs are $V_{REF} = V_{DD} / 2$.
- Timings used for IDD, IPP and IDDQ Measurement-Loop Patterns are provided in Table 37.
- Basic IDD, IPP and IDDQ Measurement Conditions are described in Table 39.
- Detailed IDD, IPP and IDDQ Measurement-Loop Patterns are described in Table 40 through Table 47.
- IDD Measurements are done after properly initializing the DDR4 SDRAM. This includes but is not limited to setting
 - RON = RZQ/7 (34 Ohm in MR1);
 - RTT_NOM = RZQ/6 (40 Ohm in MR1);
 - RTT_WR = RZQ/2 (120 Ohm in MR2);
 - RTT_PARK = Disable;
 - Qoff = 0_B (Output Buffer enabled) in MR1;
 - TDQS_t disabled in MR1;
 - CRC disabled in MR2;
 - CA parity feature disabled in MR5;
 - Gear down mode disabled in MR3
 - Read/Write DBI disabled in MR5;
 - DM disabled in MR5
- Attention: The IDD, IPP and IDDQ Measurement-Loop Patterns need to be executed at least one time before actual IDD or IDDQ measurement is started.
- Define D = {CS_n, ACT_n, RAS_n, CAS_n, WE_n} := {HIGH, LOW, LOW, LOW, LOW} ; apply BG/BA changes when directed.
- Define D# = {CS_n, ACT_n, RAS_n, CAS_n, WE_n} := {HIGH, HIGH, HIGH, HIGH, HIGH} ; apply invert of BG/BA changes when directed above.

NOTE :
 1) DIMM level Output test load condition may be different from above.

NOTE :

- 1) This parameter is not subject to production test. It is verified by design and characterization. The silicon only capacitance is validated by de-embedding the package L & C parasitic. The capacitance is measured with VDD, VDDQ, VSS, VSSQ applied with all other signal pins floating. Measurement procedure tbd.
- 2) DQ, DM_n, DQS_T, DQS_c, TDQS_T, TDQS_C. Although the DM, TDQS_T and TDQS_C pins have different functions, the loading matches DQ and DQS
- 3) This parameter applies to monolithic devices only; stacked/dual-die devices are not covered here
- 4) Absolute value CK_T-CK_C
- 5) Absolute value of CIO(DQS_T)-CIO (DQS_c)
- 6) C_I applies to ODT, CS_n, CKE, A0-A17, BA0-BA1, BG0-BG1, RAS_n/A16, CAS_n/A15, WE_n/A14, ACT_n and PAR.
- 7) C_{DI_CTRL} applies to ODT, CS_n and CKE
- 8) $C_{DI_CTRL} = C_I(CTRL) - 0.5 * (C_I(CLK_T) + C_I(CLK_C))$
- 9) C_{DI_ADD_CMD} applies to, A0-A17, BA0-BA1, BG0-BG1, RAS_n/A16, CAS_n/A15, WE_n/A14, ACT_n and PAR.
- 10) $C_{DI_ADD_CMD} = C_I(ADD_CMD) - 0.5 * (C_I(CLK_T) + C_I(CLK_C))$
- 11) $C_{DIO} = C_{IO}(DQ, DM) - 0.5 * (C_{IO}(DQS_T) + C_{IO}(DQS_c))$
- 12) Maximum external load capacitance on ZQ pin: tbd pF.
- 13) TEN pin may be DRAM internally pulled low through a weak pull-down resistor to VSS. In this case C_{TEN} might not be valid and system shall verify TEN signal with Vendor specific information.

15. ELECTRICAL CHARACTERISTICS & AC TIMING

15.1 Reference Load for AC Timing and Output Slew Rate

Figure 23 represents the effective reference load of 50 ohms used in defining the relevant AC timing parameters of the device as well as output slew rate measurements.

Ron nominal of DQ, DQS_t and DQS_c drivers uses 34 ohms to specify the relevant AC timing parameter values of the device.

The maximum DC High level of Output signal = 1.0 * VDDQ,

The minimum DC Low level of Output signal = {34 / (34 + 50)} * VDDQ = 0.4 * VDDQ

The nominal reference level of an Output signal can be approximated by the following:

The center of maximum DC High and minimum DC Low = {(1 + 0.4) / 2} * VDDQ = 0.7 * VDDQ

The actual reference level of Output signal might vary with driver Ron and reference load tolerances. Thus, the actual reference level or midpoint of an output signal is at the widest part of the output signal's eye. Prior to measuring AC parameters, the reference level of the verification tool should be set to an appropriate level.

It is not intended as a precise representation of any particular system environment or a depiction of the actual load presented by a production tester. System designers should use IBIS or other simulation tools to correlate the timing reference load to a system environment. Manufacturers correlate to their production test conditions, generally one or more coaxial transmission lines terminated at the tester electronics.

Figure 23. Reference Load for AC Timing and Output Slew Rate

15.2 tREFI

Average periodic Refresh interval (tREFI) of DDR4 SDRAM is defined as shown in the table.

[Table 53] tREFI by device density

| Parameter | Symbol | 2Gb | 4Gb | 8Gb | 16Gb | Units | NOTE | |
|---|--------|-----------------------------------|-----|-----|------|-------|------|---|
| All Bank Refresh to active/refresh cmd time | tRFC | 160 | 260 | 350 | 550 | ns | | |
| Average periodic refresh interval | tREFI | 0 °C ≤ T _{CASE} ≤ 85°C | 7.8 | 7.8 | 7.8 | 7.8 | μs | |
| | | -40 °C ≤ T _{CASE} ≤ 85°C | 7.8 | 7.8 | 7.8 | 7.8 | μs | 2 |
| | | 85 °C < T _{CASE} ≤ 95°C | 3.9 | 3.9 | 3.9 | 3.9 | μs | 1 |

- NOTE :**
- Users should refer to the DRAM supplier data sheet and/or the DIMM SPD to determine if DDR4 SDRAM devices support the following options or requirements referred to in this material.
 - Supported only for Industrial Temperature.

15.3 Clock Specification

The jitter specified is a random jitter meeting a Gaussian distribution. Input clocks violating the min/max values may result in malfunction of the DDR4 SDRAM device.

15.3.1 Definition for tCK(abs)

tCK(abs) is defined as the absolute clock period, as measured from one rising edge to the next consecutive rising edge. tCK(abs) is not subject to production test.

15.3.2 Definition for tCK(avg)

tCK(avg) is calculated as the average clock period across any consecutive 200 cycle window, where each clock period is calculated from rising edge to rising edge.

$$tCK(avg) = \left(\sum_{j=1}^N tCK(abs)_j \right) / N \quad N = 200$$

15.3.3 Definition for tCH(avg) and tCL(avg)

tCH(avg) is defined as the average high pulse width, as calculated across any consecutive 200 high pulses.

$$tCH(avg) = \left(\sum_{j=1}^N tCH_j \right) / \{N \times tCK(avg)\} \quad N = 200$$

tCL(avg) is defined as the average low pulse width, as calculated across any consecutive 200 low pulses.

$$tCL(avg) = \left(\sum_{j=1}^N tCL_j \right) / \{N \times tCK(avg)\} \quad N = 200$$

15.3.4 Definition for tERR(nper)

tERR is defined as the cumulative error across n consecutive cycles of n x tCK(avg). tERR is not subject to production test.

NOTE :

- 1) Start of internal write transaction is defined as follows :
 - For BL8 (Fixed by MRS and on-the-fly) : Rising clock edge 4 clock cycles after WL.
 - For BC4 (on-the-fly) : Rising clock edge 4 clock cycles after WL.
 - For BC4 (fixed by MRS) : Rising clock edge 2 clock cycles after WL.
- 2) A separate timing parameter will cover the delay from write to read when CRC and DM are simultaneously enabled
- 3) Commands requiring a locked DLL are: READ (and RAP) and synchronous ODT commands.
- 4) tWR is defined in ns, for calculation of tWRPDEN it is necessary to round up tWR/tCK following rounding algorithm defined in "16.1 Rounding Algorithms".
- 5) WR in clock cycles as programmed in MR0.
- 6) tREFI depends on TOPER.
- 7) CKE is allowed to be registered low while operations such as row activation, precharge, autoprecharge or refresh are in progress, but power-down IDD spec will not be applied until finishing those operations.
- 8) For these parameters, the DDR4 SDRAM device supports $t_{nPARAM}[nCK]=RU\{t_{PARAM}[ns]/t_{CK}(avg)[ns]\}$, which is in clock cycles assuming all input clock jitter specifications are satisfied.
- 9) When CRC and DM are both enabled, tWR_CRC_DM is used in place of tWR.
- 10) When CRC and DM are both enabled tWTR_S_CRC_DM is used in place of tWTR_S.
- 11) When CRC and DM are both enabled tWTR_L_CRC_DM is used in place of tWTR_L.
- 12) The max values are system dependent.
- 13) DQ to DQS total timing per group where the total includes the sum of deterministic and random timing terms for a specified BER. BER spec and measurement method are tbd.
- 14) The deterministic component of the total timing. Measurement method tbd.
- 15) DQ to DQ static offset relative to strobe per group. Measurement method tbd.
- 16) This parameter will be characterized and guaranteed by design.
- 17) When the device is operated with the input clock jitter, this parameter needs to be derated by the actual $t_{jit(per)}_{total}$ of the input clock. (output deratings are relative to the SDRAM input clock). Example tbd.
- 18) DRAM DBI mode is off.
- 19) DRAM DBI mode is enabled. Applicable to x8 and x16 DRAM only.
- 20) tQSL describes the instantaneous differential output low pulse width on DQS_t - DQS_c, as measured from on falling edge to the next consecutive rising edge
- 21) tQSH describes the instantaneous differential output high pulse width on DQS_t - DQS_c, as measured from on falling edge to the next consecutive rising edge
- 22) There is no maximum cycle time limit besides the need to satisfy the refresh interval tREFI
- 23) tCH(abs) is the absolute instantaneous clock high pulse width, as measured from one rising edge to the following falling edge
- 24) tCL(abs) is the absolute instantaneous clock low pulse width, as measured from one falling edge to the following rising edge
- 25) Total jitter includes the sum of deterministic and random jitter terms for a specified BER. BER target and measurement method are tbd.
- 26) The deterministic jitter component out of the total jitter. This parameter is characterized and guaranteed by design.
- 27) This parameter has to be even number of clocks
- 28) When CRC and DM are both enabled, tWR_CRC_DM is used in place of tWR.
- 29) When CRC and DM are both enabled tWTR_S_CRC_DM is used in place of tWTR_S.
- 30) When CRC and DM are both enabled tWTR_L_CRC_DM is used in place of tWTR_L.
- 31) After CKE is registered LOW, CKE signal level shall be maintained below VILDC for tCKE specification (Low pulse width).
- 32) After CKE is registered HIGH, CKE signal level shall be maintained above VIHDC for tCKE specification (HIGH pulse width).
- 33) Defined between end of MPR read burst and MRS which reloads MPR or disables MPR function.
- 34) Parameters apply from tCK(avg)min to tCK(avg)max at all standard JEDEC clock period values as stated in the Speed Bin Tables.
- 35) This parameter must keep consistency with Speed-Bin Tables shown in section 10.
- 36) DDR4-1600 AC timing apply if DRAM operates at lower than 1600 MT/s data rate. $UI=t_{CK}(avg).min/2$.
- 37) applied when DRAM is in DLL ON mode.
- 38) Assume no jitter on input clock signals to the DRAM.
- 39) Value is only valid for RONNOM = 34 ohms.
- 40) 1tCK toggle mode with setting MR4:A11 to 0.
- 41) 2tCK toggle mode with setting MR4:A11 to 1, which is valid for DDR4-2400 and 2666 speed grade.
- 42) 1tCK mode with setting MR4:A12 to 0.
- 43) 2tCK mode with setting MR4:A12 to 1, which is valid for DDR4-2400 and 2666 speed grade.
- 44) The maximum read preamble is bounded by tLZ(DQS)min on the left side and tDQSCK(max) on the right side. See Figure "Clock to Data Strobe Relationship" in Operation datasheet. Boundary of DQS Low-Z occur one cycle earlier in 2tCK toggle mode which is illustrated in "Read Preamble" section.
- 45) DQ falling signal middle-point of transferring from High to Low to first rising edge of DQS diff-signal cross-point
- 46) last falling edge of DQS diff-signal cross-point to DQ rising signal middle-point of transferring from Low to High
- 47) VrefDQ value must be set to either its midpoint or Vcent_DQ(midpoint) in order to capture DQ0 or DQL0 low level for entering PDA mode.
- 48) The maximum read postamble is bound by tDQSCK(min) plus tQSH(min) on the left side and tHZ(DQS)max on the right side. See Figure "Clock to Data Strobe Relationship" in Operation datasheet.
- 49) Reference level of DQ output signal is specified with a midpoint as a widest part of Output signal eye which should be approximately $0.7 * VDDQ$ as a center level of the static single-ended output peak-to-peak swing with a driver impedance of 34 ohms and an effective test load of 50 ohms to VTT = VDDQ.
- 50) For MR7 commands, the minimum delay to a subsequent non-MRS command is 5nCK.
- 51) tMPX_LH(max) is defined with respect to actual tXMP in system as opposed to tXMP(min).

16.1 Rounding Algorithms

Software algorithms for calculation of timing parameters are subject to rounding errors from many sources. For example, a system may use a memory clock with a nominal frequency of 933.33... MHz, or a clock period of 1.0714... ns. Similarly, a system with a memory clock frequency of 1066.66... MHz yields mathematically a clock period of 0.9375... ns. In most cases, it is impossible to express all digits after the decimal point exactly, and rounding must be done because the DDR4 SDRAM specification establishes a minimum granularity for timing parameters of 1 ps.

Rules for rounding must be defined to allow optimization of device performance without violating device parameters. These algorithms rely on results that are within correction factors on device testing and specification to avoid losing performance due to rounding errors.

These rules are:

- Clock periods such as tCKAVGmin are defined to 1 ps of accuracy; for example, 0.9375... ns is defined as 937 ps and 1.0714... ns is defined as 1071 ps.
- Using real math, parameters like tAAmin, tRCDmin, etc. which are programmed in systems in numbers of clocks (nCK) but expressed in units of time (in ns) are divided by the clock period (in ns) yielding a unitless ratio, a correction factor of 2.5% is subtracted, then the result is set to the next higher integer number of clocks:

$$nCK = \text{ceiling} [(parameter_in_ns / application_tCK_in_ns) - 0.025]$$

- Alternatively, programmers may prefer to use integer math instead of real math by expressing timing in ps, scaling the desired parameter value by 1000, dividing by the application clock period, adding an inverse correction factor of 97.4%, dividing the result by 1000, then truncating down to the next lower integer value:

$$nCK = \text{truncate} [((parameter_in_ps \times 1000) / (application_tCK_in_ps) + 974) / 1000]$$

- Either algorithm yields identical results

16.2 The DQ input receiver compliance mask for voltage and timing

The DQ input receiver compliance mask for voltage and timing is shown in the figure below. The receiver mask (Rx Mask) defines area the input signal must not encroach in order for the DRAM input receiver to be expected to be able to successfully capture a valid input signal with BER of 1e-16; any input signal encroaching within the Rx Mask is subject to being invalid data. The Rx Mask is the receiver property for each DQ input pin and it is not the valid data-eye.

Figure 24. DQ Receiver(Rx) compliance mask

Figure 25. Vcent_DQ Variation to Vcent_DQ(midpoint)

The Vref_DQ voltage is an internal reference voltage level that shall be set to the properly trained setting, which is generally Vcent_DQ(midpoint), in order to have valid Rx Mask values.

Vcent_DQ is defined as the midpoint between the largest Vref_DQ voltage level and the smallest Vref_DQ voltage level across all DQ pins for a given DDR4 DRAM component. Each DQ pin Vref level is defined by the center, i.e. widest opening, of the cumulative data input eye as depicted in Figure 25. This clarifies that any DDR4 DRAM component level variation must be accounted for within the DDR4 DRAM Rx mask. The component level Vref will be set by the system to account for Ron and ODT settings.

Figure 26. DQS to DQ and DQ to DQ Timings at DRAM Balls

All of the timing terms in Figure 26 are measured at the V_{diVW} voltage levels centered around V_{cent_DQ} and are referenced to the DQS_t/DQS_c center aligned to the DQ per pin.

The rising edge slew rates are defined by srr1 and srr2. The slew rate measurement points for a rising edge are shown in Figure 27 below: A low to high transition tr1 is measured from 0.5*VdiVW(max) below Vcent_DQ(midpoint) to the last transition through 0.5*VdiVW(max) above Vcent_DQ(midpoint) while tr2 is measured from the last transition through 0.5*VdiVW(max) above Vcent_DQ(midpoint) to the first transition through the 0.5*VIHL_AC(min) above Vcent_DQ(midpoint).

Rising edge slew rate equations:

$$srr1 = VdiVW(max) / tr1$$

$$srr2 = (VIHL_AC(min) - VdiVW(max)) / (2*tr2)$$

Figure 27. Slew Rate Conditions For Rising Transition

The falling edge slew rates are defined by srf1 and srf2. The slew rate measurement points for a falling edge are shown in Figure 28 below: A high to low transition tf1 is measured from 0.5*VdiVW(max) above Vcent_DQ(midpoint) to the last transition through 0.5*VdiVW(max) below Vcent_DQ(midpoint) while tf2 is measured from the last transition through 0.5*VdiVW(max) below Vcent_DQ(midpoint) to the first transition through the 0.5*VIHL_AC(min) below Vcent_DQ(pin mid).

Falling edge slew rate equations:

$$srf1 = VdiVW(max) / tf1$$

$$srf2 = (VIHL_AC(min) - VdiVW(max)) / (2*tf2)$$

NOTE :

- 1) Data Rx mask voltage and timing total input valid window where VdIVW is centered around Vcent_DQ(midpoint) after VrefDQ training is completed. The data Rx mask is applied per bit and should include voltage and temperature drift terms. The input buffer design specification is to achieve at least a BER = e-16 when the RxMask is not violated. The BER will be characterized and extrapolated if necessary using a dual dirac method from a higher BER(tbd).
- 2) Defined over the DQ internal Vref range 1.
- 3) See Overshoot and Undershoot Specifications.
- 4) DQ input pulse signal swing into the receiver must meet or exceed VIHL AC(min). VIHL_AC(min) is to be achieved on an UI basis when a rising and falling edge occur in the same UI, i.e. a valid TdiPW.
- 5) DQ minimum input pulse width defined at the Vcent_DQ(midpoint).
- 6) DQS to DQ offset is skew between DQS and DQs within a nibble (x4) or word (x8, x16) at the DDR4 SDRAM balls over process, voltage, and temperature.
- 7) DQ to DQ offset is skew between DQs within a nibble (x4) or word (x8, x16) at the DDR4 SDRAM balls for a given component over process, voltage, and temperature.
- 8) Input slew rate over VdIVW Mask centered at Vcent_DQ(midpoint). Slowest DQ slew rate to fastest DQ slew rate per transition edge must be within 1.7 V/ns of each other.
- 9) Input slew rate between VdIVW Mask edge and VIHL_AC(min) points.
- 10) All Rx Mask specifications must be satisfied for each UI. For example, if the minimum input pulse width is violated when satisfying TdiVW(min), VdiVW(max), and minimum slew rate limits, then either TdiVW(min) or minimum slew rates would have to be increased to the point where the minimum input pulse width would no longer be violated.

16.3 Command, Control, and Address Setup, Hold, and Derating

The total tIS (setup time) and tIH (hold time) required is calculated to account for slew rate variation by adding the data sheet tIS (base) values, the VIL(AC)/VIH(AC) points, and tIH (base) values, the VIL(DC)/VIH(DC) points; to the ΔtIS and ΔtIH derating values, respectively. The base values are derived with single-end signals at 1V/ns and differential clock at 2V/ns. Example: tIS (total setup time) = tIS (base) + ΔtIS .

For a valid transition, the input signal has to remain above/below VIH(AC)/VIL(AC) for the time defined by tVAC.

Although the total setup time for slow slew rates might be negative (for example, a valid input signal will not have reached VIH(AC)/VIL(AC) at the time of the rising clock transition), a valid input signal is still required to complete the transition and to reach VIH(AC)/VIL(AC). For slew rates that fall between the values listed in derating tables, the derating values may be obtained by linear interpolation.

Setup (tIS) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VIL(DC)max and the first crossing of VIH(AC)min that does not ring back below VIH(DC)min. Setup (tIS) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VIH(DC)min and the first crossing of VIL(AC)max that does not ring back above VIL(DC)max. Hold (tIH) nominal slew rate for a rising signal is defined as the slew rate between the last crossing of VIL(DC)max and the first crossing of VIH(AC)min that does not ring back below VIH(DC)min. Hold (tIH) nominal slew rate for a falling signal is defined as the slew rate between the last crossing of VIH(DC)min and the first crossing of VIL(AC)min that does not ring back above VIL(DC)max.
